Computer Viewing

CS 537 Interactive Computer Graphics
Prof. David E. Breen
Department of Computer Science
Objectives

- Introduce the mathematics of projection
- Introduce OpenGL viewing functions
- Look at alternate viewing APIs
There are three aspects of the viewing process, all of which should be implemented in the pipeline,

- Positioning the camera
  - Setting the model-view matrix
- Selecting a lens
  - Setting the projection matrix
- Clipping
  - Setting the view volume
The OpenGL Camera

• In OpenGL, initially the object and camera frames are the same
  - Default model-view matrix is an identity
• The camera is located at origin and points in the negative z direction
• OpenGL also specifies a default view volume that is a cube with sides of length 2 centered at the origin
  - Default projection matrix is an identity
Default Projection

Default projection is orthographic

- Projection plane $z=0$
- Clipped out
Moving the Camera Frame

• If we want to visualize objects with both positive and negative z values we can either
  - Move the camera in the positive z direction
    • Translate the camera frame
  - Move the objects in the negative z direction
    • Translate the world frame

• Both of these views are equivalent and are determined by the model-view matrix
  - Want a translation \( \text{Translate}(0.0,0.0,-d); \)
    \(-d > 0\)
Moving Camera back from Origin

frames after translation by \(-d\), \(d > 0\)

default frames

(a)  

(b)
Moving Camera back from Origin

frames after translation by \(-d\) 
\(d > 0\)

default frames

World is actually being moved relative to camera frame.
Moving the Camera

• We can move the camera to any desired position by a sequence of rotations and translations

• Example: side view
  - Rotate the scene
  - Move it away from origin
  - Model-view matrix $C = TR$
OpenGL code

• Remember that last transformation specified is first to be applied

```
// Using mat.h

mat4 t = Translate(0.0, 0.0, -d);
mat4 ry = RotateY(-90.0);
mat4 m = t*ry;
```

This is code for moving world frame relative to camera frame. It is the inverse of the desired camera movement.
The LookAt Function

• The GLU library contained the function gluLookAt to form the required modelview matrix through a simple interface

• Note the need for setting an up direction
  - Should not be parallel to look-at direction

• Replaced by LookAt() in mat.h
  - Can concatenate with modeling transformations

• Example: isometric view of cube aligned with axes

```
mat4 mv = LookAt(vec4 eye, vec4 at, vec4 up);
```
LookAt(eye, at, up)
  eye – location of camera
  at – look-at point
  up – up vector

\[(\text{eye}_x, \text{eye}_y, \text{eye}_z)\]

\[(\text{at}_x, \text{at}_y, \text{at}_z)\]

\[(u_p_x, u_p_y, u_p_z)\]
Other Viewing APIs

• The LookAt function is only one possible API for positioning the camera
• Others include
  - View reference point, view plane normal, view up (PHIGS, GKS-3D)
  - Yaw, pitch, roll
  - Elevation, azimuth, twist
  - Direction angles
Projections and Normalization

• The default projection in the eye (camera) frame is orthographic

• For points within the default view volume

\[
\begin{align*}
x_p &= x \\
y_p &= y \\
z_p &= 0
\end{align*}
\]

• Most graphics systems use view normalization
  - All other views are converted to the default view by transformations that determine the projection matrix
  - Allows use of the same pipeline for all views
Homogeneous Coordinate Representation

default orthographic projection

\[ x_p = x \]
\[ y_p = y \]
\[ z_p = 0 \]
\[ w_p = 1 \]

\[ p_p = Mp \]

\[ M = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix} \]

In practice, we can let \( M = I \) and set the \( z \) term to zero later.
Simple Perspective

- Center of projection at the origin
- Projection plane $z = d, d < 0$
Perspective Equations

Consider top and side views

\[ x_p = \frac{x}{z/d} \quad y_p = \frac{y}{z/d} \quad z_p = d \]
Homogeneous Coordinate Form

consider $q = Mp$ where $M = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 1/d & 0
\end{bmatrix}$

$q = \begin{bmatrix}
x \\
y \\
z \\
1
\end{bmatrix}$ \Rightarrow \quad p = \begin{bmatrix}
x \\
y \\
z \\
z/d
\end{bmatrix} = \begin{bmatrix}
x/(z/d) \\
y/(z/d) \\
d \\
1
\end{bmatrix}$
Perspective Division

• However \( w \neq 1 \), so we must divide by \( w \) to return from homogeneous coordinates

• This *perspective division* yields

\[
x_p = \frac{x}{z/d} \quad y_p = \frac{y}{z/d} \quad z_p = d
\]

the desired perspective equations

• We will consider the corresponding clipping volume with *mat.h* functions that are equivalent to deprecated OpenGL functions
OpenGL Orthogonal Viewing

Ortho(left, right, bottom, top, near, far)

near and far measured from camera
View volume specified in camera coordinates
OpenGL Perspective

Frustum(left, right, bottom, top, near, far)

Specified in camera coordinates
Using Field of View

- With Frustum it is often difficult to get the desired view

- Perspective($\text{fovy, aspect, near, far}$) often provides a better interface

\[
\text{aspect} = \frac{w}{h}
\]
Projection Matrices

CS 537 Interactive Computer Graphics
Prof. David E. Breen
Department of Computer Science
Objectives

- Derive the projection matrices used for standard OpenGL projections
- Introduce oblique projections
- Introduce projection normalization
Normalization

• Rather than derive a different projection matrix for each type of projection, we can convert all projections to orthogonal projections with the default view volume.

• This strategy allows us to use standard transformations in the pipeline and makes for efficient clipping.
Pipeline View

- modelview transformation
- projection transformation
- perspective division
- clipping
- projection

4D → 3D
3D → 2D

against default cube

nonsingular vertex shader output
Notes

• We stay in four-dimensional homogeneous coordinates through both the modelview and projection transformations
  - Both these transformations are nonsingular
  - Default to identity matrices (orthogonal view)

• Normalization lets us clip against simple cube regardless of type of projection

• Delay final projection until end
  - Important for hidden-surface removal to retain depth information as long as possible
Orthographic Normalization

Ortho(\texttt{left, right, bottom, top, near, far})

normalization ⇒ find transformation to convert specified clipping volume to default

\begin{align*}
(\texttt{right, top, -far}) & \quad (1, 1, -1) \\
(\texttt{left, bottom, -near}) & \quad (-1, -1, 1)
\end{align*}

left < right \quad bottom < top \quad near < far
**Orthographic Matrix**

- Two steps
  - Move center to origin
    \[ T(-\frac{\text{left} + \text{right}}{2}, -\frac{\text{bottom} + \text{top}}{2}, \frac{\text{near} + \text{far}}{2}) \]
  - Scale to have sides of length 2
    \[ S(\frac{2}{\text{left} - \text{right}}, \frac{2}{\text{top} - \text{bottom}}, \frac{2}{\text{near} - \text{far}}) \]

\[
P = ST = \begin{bmatrix}
\frac{2}{\text{right} - \text{left}} & 0 & 0 & \frac{-\text{right} + \text{left}}{\text{right} - \text{left}} \\
0 & \frac{2}{\text{top} - \text{bottom}} & 0 & \frac{-\text{top} + \text{bottom}}{\text{top} - \text{bottom}} \\
0 & 0 & \frac{2}{\text{near} - \text{far}} & \frac{-\text{far} + \text{near}}{\text{far} - \text{near}} \\
0 & 0 & 0 & 1
\end{bmatrix}
\]
Final Projection

• Set $z = 0$

• Equivalent to the homogeneous coordinate transformation

\[
M_{\text{orth}} = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
\]

• Hence, general orthographic projection in 4D is

\[
P = M_{\text{orth}} \overline{ST}
\]
Oblique Projections

• The OpenGL projection functions cannot produce general parallel projections such as...

• However if we look at the example of the cube it appears that the cube has been sheared...

• Oblique Projection = Shear + Orthographic Projection
General Shear
Shear Matrix

(xy shear (z values unchanged))

\[ H(\theta,\phi) = \begin{bmatrix} 1 & 0 & -\cot \theta & 0 \\ 0 & 1 & -\cot \varphi & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

Projection matrix

\[ P = M_{\text{orth}} H(\theta,\phi) \]

General case: \[ P = M_{\text{orth}} \text{STH}(\theta,\phi) \]
Equivalency
Effect on Clipping

- The projection matrix \( \mathbf{P} = \mathbf{STH} \) transforms the original clipping volume to the default clipping volume.

- Distorted object (projects correctly).

- Near plane:
  - \( x = -1 \)
  - \( z = -1 \)

- Far plane:
  - \( x = 1 \)
  - \( z = 1 \)
Simple Perspective

Consider a simple perspective with the COP at the origin, the near clipping plane at $z = -1$, and a 90 degree field of view determined by the planes $x = \pm z, y = \pm z$
Perspective Matrices

Simple projection matrix in homogeneous coordinates

\[
\mathbf{M} = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & -1 & 0
\end{bmatrix}
\]

\[x' = x \quad x' = -\frac{x}{z}
\]
\[y' = y \quad y' = -\frac{y}{z}
\]
\[z' = z \quad z' = -1
\]
\[w' = -z
\]

Note that this matrix is independent of the far clipping plane
Generalization

\[ N = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \alpha & \beta \\ 0 & 0 & -1 & 0 \end{bmatrix} \]

\[ x' = x \]
\[ y' = y \]
\[ z' = \alpha z + \beta \]
\[ w' = -z \]

after perspective division, the point \((x, y, z, 1)\) goes to

\[ x'' = -x/z \]
\[ y'' = -y/z \]
\[ z'' = -(\alpha + \beta/z) \]

which projects orthogonally to the desired point regardless of \(\alpha\) and \(\beta\)
Picking $\alpha$ and $\beta$

If we pick

$$z^{''} = -\left(\alpha + \beta/z\right)$$

$$\alpha = \frac{\text{near} + \text{far}}{\text{far} - \text{near}}$$

$$\beta = \frac{2\text{near} \times \text{far}}{\text{near} - \text{far}}$$

the near plane is mapped to $z = -1$
the far plane is mapped to $z = 1$
and the sides are mapped to $x = \pm 1$, $y = \pm 1$

Hence the new clipping volume is the default clipping volume
Normalization Transformation

original clipping volume

original object

new clipping volume

distorted object projects correctly

$z = -x$

$z = x$

$z = -\text{far}$

$z = -\text{near}$

COP

$x = -1$

$x = 1$

$z = 1$

$z = -1$
Normalization and Hidden-Surface Removal

• Although our selection of the form of the perspective matrices may appear somewhat arbitrary, it was chosen so that if \( z_1 > z_2 \) in the original clipping volume then the for the transformed points \( z'_1 > z'_2 \)
• Thus hidden surface removal works if we first apply the normalization transformation
• However, the formula \( z'' = -(\alpha + \beta/z) \) implies that the distances are distorted by the normalization which can cause numerical problems especially if the near distance is small
Frustum allows for an unsymmetric viewing frustum (although Perspective does not)

Frustum(left, right, bottom, top, near, far)

\[ Z = Z_{\text{min}} \]

\[ (x_{\text{min}}, y_{\text{min}}, z_{\text{max}}) \]

\[ (x_{\text{max}}, y_{\text{max}}, z_{\text{max}}) \]

left < right    bottom < top    near < far
near & far positive
OpenGL Perspective

- **Perspective** provides less flexible, but more intuitive perspective viewing
  `Perspective(fov, aspect, near, far);`

- Field of view in angles
- aspect: w/h
- near < far, both positive
OpenGL Perspective Matrix

- The normalization in Frustum requires an initial shear to form a right viewing pyramid, followed by a scaling to get the normalized perspective volume. Finally, the perspective matrix results in needing only a final orthographic transformation.

\[ P = \text{NSH} \]

our previously defined perspective matrix shear and scale
Why do we do it this way?

- Normalization allows for a single pipeline for both perspective and orthogonal viewing.
- We stay in four dimensional homogeneous coordinates as long as possible to retain three-dimensional information needed for hidden-surface removal and shading.
- We simplify clipping.
Viewing OpenGL Code

• It’s not too bad, thanks to Ed Angel

• In application

\[
\text{model\_view} = \text{LookAt}(\text{eye}, \text{at}, \text{up})
\]
\[
\text{projection} = \text{Ortho}(\text{left}, \text{right}, \text{bottom}, \text{top}, \text{near}, \text{far})
\]

or

\[
\text{projection} = \text{Perspective}(\text{fov}, \text{aspect}, \text{near}, \text{far})
\]

• In vertex shader

\[
\text{gl\_Position} = \text{projection*model\_view*vPosition}
\]
OpenGL code

• Remember that matrices are column major order in GLSL, so …

Transpose your matrices when sending them to the shaders!

```c
glUniformMatrix4fv(matrix_loc, 1, GL_TRUE,
                    model_view);
```
Simple Mesh Format (SMF)

- Michael Garland  
  http://graphics.cs.uiuc.edu/~garland/

- Triangle data
- List of 3D vertices
- List of references to vertex array
  define faces (triangles)

- Vertex indices begin at 1
Normal for Triangle

plane \quad \mathbf{n} \cdot (\mathbf{p} - \mathbf{p}_0) = 0

\mathbf{n} = (\mathbf{p}_2 - \mathbf{p}_0) \times (\mathbf{p}_1 - \mathbf{p}_0)

normalize \ \mathbf{n} \quad \leftarrow \ \mathbf{n}/ |\mathbf{n}|

Note that right-hand rule determines outward face
Suggestions for HW5

• Read in smf files & test with HW4
• Transform centroid of bounding box to origin
• Calculate normal for each triangle
• Use normalized normal as color for triangle
  - Be sure to take absolute value
• Each triangle vertex will need its own color
  - This color is passed to the fragment shader
• Next implement LookAt feature
• Test with fixed eye point and orthographic projection
Suggestions for HW5

• Make sure that your model is in the view volume defined by your ortho() function
• Recall that your view volume is defined in camera coordinates
• Send model-view and projection matrix to the vertex shader via uniform variable
• You should now be displaying an orthographic projection from an arbitrary camera location/orientation
Suggestions for HW5

• Implement perspective projection
  - Think about the parameter values you use
• Define menu that allows user to pick projection type
• Make camera move with a keyboard() function
• User should be able to change the angle, height and radius of the camera location (in cylindrical coordinates)
