

# CS 360 - Introduction to Haskell

Mark Boady

July 25, 2013

## Quiz/Homework Notes

- ▶ Answer all of multipart questions.
- ▶ Non-Tail Recursive Length

```
(define (length L)
  (if (null? L)
      0
      (+ 1 (length (cdr L)))))
)
```

## Quiz/Homework Notes

- ▶ Tail recursive Length

```
(define (len L n)
  (if (null? L)
      n
      (len (cdr L) (+ 1 n))))
)
(define (length L) (len L 0))
```

# Haskell

- ▶ GHCi is installed on tux ([www.haskell.org](http://www.haskell.org))
  - ▶ ghci
- ▶ To quit
  - ▶ Ctrl-D (end of file)
  - ▶ :quit (Note the colon before the work!)
- ▶ Load Files
  - ▶ You can load files from the current directory
  - ▶ :load fact.hs

# Math Functions

- ▶ The basic math functions use infix notation

```
Prelude> 9*10
```

```
90
```

```
Prelude> 9 + 8
```

```
17
```

```
Prelude> 10-20
```

```
-10
```

```
Prelude> 4 < 5
```

```
True
```

```
Prelude> 10-1.1
```

```
8.9
```

## Defining Functions

- ▶ Defining a variable
  - ▶ `let x = 10`
- ▶ Defining a function
  - ▶ `let gcd1 u v = if v == 0 then u else gcd1 v (mod u v)`

- ▶ Calling a function

```
Prelude> gcd1 100 15
```

- ▶ Defining multi-line functions in the interpreter requires special syntax

```
Prelude> :{  
Prelude| let { fact 0 = 1  
Prelude| ; fact n = n * fact (n-1)  
Prelude| }  
Prelude| :}
```

## Loading Files

- ▶ You can easily define functions in files and load them
- ▶ The contents of a file fact.hs

```
fact 0 = 1
fact n = n * fact ( n-1)
```

- ▶ Running it in Haskell

```
Prelude> :load fact.hs
[1 of 1] Compiling Main ( fact.hs, interpreted )
Ok, modules loaded: Main.
*Main> fact 34
295232799039604140847618609643520000000
```

## Currying

- ▶ We can make new functions by applying a function with fewer inputs than required.
- ▶ The addition symbol takes two inputs  $A+B$
- ▶ We can make a `plus1` function by only giving the plus symbol one input
  - ▶ `let plus1 = (1+)`
- ▶ This works with higher order functions to
  - ▶ `let square_list = map (\x -> x * x)`
- ▶ The lambda syntax of Haskell is used above
  - ▶ `(\x -> x * x)`
- ▶ We can compose functions using the dot operator

```
*Main> let secretfunction = ((*3) . (2+))
```

```
*Main> secretfunction 5
```

```
21
```

# List Commands

- ▶ Concat
  - ▶ 1 : [2,3,4]
- ▶ Merge
  - ▶ [1,2,3] ++ [4.5.6]
- ▶ Get the first element (car)
  - ▶ head [1,2,3]
- ▶ Get all but the head (cdr)
  - ▶ tail [1,2,3]
- ▶ We can save code with pattern matching like in ML
  - ▶ let (h:t) = [1,2,3,4]
- ▶ Null Test
  - ▶ null []

## Advanced Lists

- ▶ There is a special shorthand for mapping over lists
  - ▶ `let square_list list = [ x * x | x <- list]`
- ▶ All evaluation is lazy, so infinite lists aren't a problem
  - ▶ `let ones = 1 : ones`
- ▶ We can use `take` and `drop` to get a subset of an infinite list
  - ▶ `take 30 ones`
  - ▶ `take 5 (drop 4 [2..])`
- ▶ The command `[2..]` gives all integers starting at 2

# Finding all Primes

- ▶ The list of all primes is infinite
- ▶ It is a filtered version of all integers
- ▶ The **Sieve of Eratosthenes** filters primes out of the list of integers

```
let sieve (p:lis) = p :  
    sieve [n | n <- lis, mod n p /= 0]  
let primes = sieve [2..]
```

## Twin Primes

- ▶ A twin prime is a prime  $p$  where  $p+2$  or  $p-2$  is also prime.
- ▶ We can tell if something is prime by searching our prime list

```
let orderedSearch a (h:t) = if a < h then False
                             else (if a == h then True
                                   else orderedSearch a t )
```

- ▶ Now, we can ask if a number is a twin prime.

```
let isTwinPrime a = (orderedSearch (a+2) primes)
                    || (orderedSearch (a-2) primes)
```

- ▶ We have a boolean function telling us which numbers to keep.

```
let tprimes = filter isTwinPrime primes
```

# Programming Assignment 1

- ▶ Due 7/30/13 by midnight
- ▶ Scheme Functions
  - ▶ range
  - ▶ sequence
  - ▶ iterator
  - ▶ lookup
  - ▶ lookup-env
- ▶ Review Submission Guidelines
