ENGR 541
Project: Reliability of a Consecutive $k$-out-of-$r$-from-$n$ System
Algorithm & Visualization

Zexi Liu
zexi@temple.edu

27th November 2006
1 Introduction

The purpose of this project was to simulate and visualize the reliability calculation of a consecutive $k$-out-of-$r$-from-$n$ system with multiple failure criteria. In the model I chose, the system consists of $n$ linearly ordered elements, and fails iff in any group of $r_1, r_2, \ldots, r_H$ consecutive elements less than $k_1, k_2, \ldots, k_H$ elements respectively are in working state. The algorithm for system reliability evaluation is based on an extended universal moment generating function.

Index Terms – Consecutive $k$-out-of-$r$-from-$n$ system, multiple failure criteria, universal moment generating function

NOTATION

$n$ number of elements in the system
$k, r$ vectors representing failure criteria in the system
$H$ Number of failure criteria in the system
$r_H$ maximal element of vector $r$
$p$ probability that the system element is in working state
$R$ system reliability

In the multi-criteria linear consecutive $k$-out-of-$r$-from-$n$ system model, $k = \{k_i | 1 \leq i \leq H\}$ & $r = \{r_i | 1 \leq i \leq H\}$ are integer vectors such that $r_i \leq n$ & $k_i \leq r_i$. The system fails if at least one group of $r_i$ consecutive elements exists in which less than $k_i$ elements are in working condition for any $1 \leq i \leq H$.

All $n$ ordered elements in the system are identical and mutually s-independent. The state of each system element $j$ is characterized by a random binary variable $X_j$, where $X_j = 0$ corresponds to failure, and $X_j = 1$ corresponds to the working state. The probability of being in the working state is $p = \Pr \{X_j = 1\}$. The system fails if for any $1 \leq i \leq H$ at least one of the sums

$$\sum_{j=1}^{r_1} X_j, \sum_{j=2}^{r_1+1} X_j, \ldots, \sum_{j=n-r_H+1}^{n} X_j$$

is less than $k_i$. The system reliability is, therefore, defined as follows: $R = \Pr \{ \sum_{j=i}^{h+r-1} X_j \geq k_i | 1 \leq h \leq n-r_i+1, 1 \leq i \leq H \}$. It can be easily seen that if there
exists an I for which \( k_i = r_i \), the system becomes a series system, and its reliability is equal to \( p^n \).

Indeed, the condition \( k_i = r_i \) means that any set of \( r_i \) consecutive elements should not contain failure elements.

2 Reliability Evaluation Algorithm

Note that the system considered contains exactly \( n - r + 1 \) groups of \( r \) consecutive elements, and each element can belong to no more than \( r \) such groups. To obtain the vector-\( u \)-functions corresponding to all the groups of \( r \) consecutive elements, the following procedure is introduced:

a) Define the vector-\( u \)-function \( U_{1-r} (z) \) as follows

\[
U_{1-r} (z) = z^{y_0}, \quad \text{where the vector } y_0 \text{ consists } r \text{ zeros.}
\]

b) Define the following shift operator \( \Psi \) over vector-\( u \)-function \( U_{h-r} (z) \):

\[
\Psi(U_{h-r} (z)) = \Psi \left( \sum_{m=1}^{2^r} Q_m z^{y_{m-h}} \right) = p \sum_{m=1}^{2^r} Q_m z^{\phi(y_{m-r}, 0)} + (1-p) \sum_{m=1}^{2^r} Q_m z^{\phi(y_{m-r}, 1)}, \quad \text{where operator } \phi(y, x) \text{ over an arbitrary vector } y \text{ & value } x \text{ shifts all the vector elements one position left: } y(j-1) = y(j) \text{ for } 1 < j \leq r, \text{ and assigns the value } x \text{ to the last element of } y: y(r) = x. \text{ The first element of vector } y \text{ disappears after applying the operator. The operator } \phi \text{ removes the state of the first element of the group, and adds the state of the next (not considered yet) element to the group preserving the order of elements belonging to the group. Therefore, applying the operator } \Psi \text{ over the vector-\( u \)-function representing the state distribution of the } h^{th} \text{ group, one obtains the vector-\( u \)-function representing the state distribution of the } (h+1)^{th} \text{ group. Using the operator } \Psi \text{ in sequence as follows:}

\[
U_{j+1-r} (z) = \Psi (U_{j-r} (z)), \quad \text{for } j = 1, \ldots, n \text{ one obtains vector-\( u \)-functions for all of the possible groups of } r \text{ consecutive elements: } U_{1-r} (z), \ldots, U_{n-r+1-r} (z).
\]

c) Define the operator \( \delta_r \) over vector-\( u \)-function \( U_{h-r} (z) \):

\[
\delta_r (U_{h-r} (z)) = \sum_{m=1}^{2^r} Q_m 1 \left( \sum_{j=1}^{r} y_{m-h} (j) < k \right) \quad \text{where } 1(x) = \begin{cases} 1, & \text{x is true} \\ 0, & \text{x is false} \end{cases}
\]

d) Apply the operator \( \delta_r \) to the vector-\( u \)-function \( U_{h-r} (z) \), we can obtain the probability that the group consisting of \( r \) elements \( h + r_H - r, \ldots, h + r_H - 1 \) fails. Note that if for some combination of elements states this group fails, the entire system fails independently of the states of the elements.
that do not belong to this group. Therefore the terms corresponding to the group failure can be removed from the vector-u-function $U_{h,1}(z)$ because they should not participate in determining further state combinations which cause system failures. This consideration lies at the base of the following algorithm, which evaluates the system reliability using an enumerative technique to obtain all of the possible element state combinations leading to the system’s failure.

The following algorithm finds the reliability of a consecutive $k$-out-of-$r$-from-$n$ system:

1) Initialization:

\[ F = 0; \quad U_{1-r_H,r_H}(z) = z^{r_H} \quad (y_0 \text{ consists of } r_H \text{ zeros}). \]

2) Main loop:

Repeat the following for $j = 1, \ldots, n$:

2.1. Obtain $U_{j+1-r_H,r_H}(z) = \Psi(U_{j-r_H,r_H}(z))$, and collect like terms in the obtained vector-u-function.

2.2. For $i = 1, \ldots, H$ if $j \geq r_i$, add the value $\delta_i(U_{j+1-r_H,r_H}(z))$ to $F$, and remove all of the terms with $\sum_{k=r_H - r_{j+1}}^{r_H} y(s) < k_i$ from $U_{j+1-r_H,r_H}(z)$.

3) Obtain the system reliability as $R = 1 - F$. Alternatively, the system reliability can be obtained as the sum of the coefficients of the last vector-u-function $U_{n+1-r_H,r_H}(z)$.

3 Matlab Calculation

In the Matlab program, the above algorithm should be changed a little bit. However, the basic idea is the same.

1) Define two initial matrix $U_z$ and $U_p$ as follows:

\[ U_z = [z_1 \ z_2 \ \ldots \ z_r], \quad z_1 = 0 \quad z_2 = 0 \ \ldots \ z_r = 0 \text{ consists of } r_H \text{ zeros}. \]

\[ U_p = [1-p_1 \ p_1], \quad p_1 \text{ is the probability that the } 1^{st} \text{ element is in working state}. \]
II) Define the following shift function \( \text{shift}() \) and \( \text{shiftp}() \) over \( U_z \) and \( U_p \) as follows:

\[
\text{shift} (U_z) = \begin{bmatrix}
[U_z]_{ix,j} & [0]_{ix,1} \\
[U_z]_{ix,j} & [1]_{ix,1}
\end{bmatrix} = \begin{bmatrix}
z_2 & z_3 & \cdots & z_r & 0 \\
z_2 & z_3 & \cdots & z_r & 1
\end{bmatrix}, \text{note that the first column was deleted.}
\]

\[
\text{shiftp} (U_p) = \begin{bmatrix}
[U_p]_{ix,j} & [1-p_2]_{ix,1} \\
[U_p]_{ix,j} & [p_2]_{ix,1}
\end{bmatrix} = \begin{bmatrix}
1-p_1 & p_1 & 1-p_2 \\
1-p_1 & p_1 & p_2
\end{bmatrix}, \text{1-p_2 is corresponding to 0 in the above matrix, p_2 is corresponding to 1 in the above matrix.}
\]

III) Define the following removal function \( \text{truncate} (U_z, U_p, k_i, r_i, r_H) \) as follows:

If \( \sum_{r=r_i + r_i + 1}^{j} U_{z,m,r} < k_j \), then remove the \( m^{th} \) row of both matrix \( U_z \) and \( U_p \). \( m = 1, \ldots, \) number of rows of \( U_z \). \( j \) is the number of columns of \( U_z \).

IV) Repeat the main loop \( n \) times.

V) The system reliability can be obtained from the following equation:

\[
\text{Reliability} = \sum_{m=1}^{i} \left( \prod_{k=1}^{j} U_{p,m,k} \right), \text{where } i, j \text{ is the size of } U_p_{ix,j}
\]
4 Simulation & Visualization

Let’s take the \((k_1, k_2, k_3)\)-out-of-(5, 7, 8)-from-9 system as an example.

1) \(P = [p_1 \, p_2 \, p_3 \ldots \, p_9]\) are constant i.e. \(p_1 = p_2 = \ldots = p_9 = \text{Constant}\).

Let Constant = 0.8

Plot 3-D bar charts as follows.

Fig. 1. Uniform Distribution of system elements

Fig. 2. Reliability of \((k_1, k_2, k_3)\)-out-of-(5, 7, 8)-from-9 system as function of \(k_1, k_2, k_3\).
2) \( P = [p_1, p_2, p_3, \ldots, p_n] \) are linearly increasing. \( n = 9, p_1 = 0.6, p_n = 0.9, \)

\[
P_i = \left( \frac{p_n - p_i}{n-1} \right) (i-1) + p_i
\]

Plot 3-D bar charts as follows.

Fig. 3. Probability Distribution of system elements

Fig. 4. Reliability of \((k_1, k_2, k_3)\)-out-of-(5, 7, 8)-from-9 system as function of \( k_1, k_2, k_3 \).
3) \( P = [p_1; p_2; \ldots; p_n] \) are exponentially increasing. \( n = 9, i = 1, 2, \ldots, 9, \lambda = 0.4 \) \( p_i = \lambda \times e^{-\lambda \times i} \).

Plot 3-D bar charts as follows.

Fig. 5. Exponential Distribution

Fig. 6. Reliability of \((k_1, k_2, k_3)\)-out-of-(5, 7, 8)-from-9 system as function of \(k_1, k_2, k_3\).
4) \( P = [p_1 \ p_2 \ p_3 \ \ldots \ p_n] \) are Gaussian distribution. \( n = 9 \), \( i = 1, 2, \ldots, 9 \), \( \mu = (n+1)/2, \sigma = 2.5 \)

\[
p_i = 3.5 \times \frac{1}{\sqrt{2\pi \sigma^2}} e^{-\frac{(i-\mu)^2}{2\sigma^2}}.
\]

Plot 3-D bar charts as follows.

---

**Fig. 7. Gaussian Distribution**

**Fig. 8. Reliability of \((k_1, k_2, k_3)\)-out-of-(5, 7, 8)-from-9 system as function of \(k_1, k_2, k_3\).**
5) \( P = [p_1, p_2, p_3 \ldots p_n] \) are not assigned any value.

\( K = [1 \ 2 \ 7], \ R = [5 \ 7 \ 8], \ n = 9 \ (K_3 \neq R_3) \)

\( P = [p_1, p_2, p_3, p_4, p_5, p_6, p_7, p_8, p_9] \)

System Reliability

\[
(1-p_1)*p_2*p_3*p_4*p_5*p_6*p_7*p_8*\ldots*(1-p_9)+p_1*p_2*p_3*p_4*p_5*p_6*p_7*p_8*(1-p_9)+p_1*p_2*p_3*p_4*p_5*p_6*p_7*p_8*(1-p_9)+p_1*p_2*p_3*p_4*p_5*p_6*p_7*p_8*(1-p_9)+p_1*p_2*p_3*p_4*p_5*p_6*p_7*p_8*(1-p_9)
\]

\[
\begin{bmatrix}
1-p_1 & p_2 & p_3 & p_4 & p_5 & p_6 & p_7 & p_8 & 1-p_9 \\
p_1 & p_2 & p_3 & p_4 & p_5 & p_6 & p_7 & 1-p_8 & p_9 \\
p_1 & p_2 & p_3 & p_4 & p_5 & p_6 & 1-p_7 & p_8 & p_9 \\
p_1 & p_2 & p_3 & p_4 & 1-p_5 & p_6 & p_7 & p_8 & p_9 \\
p_1 & p_2 & 1-p_3 & p_4 & p_5 & p_6 & p_7 & p_8 & p_9 \\
1-p_1 & p_2 & p_3 & p_4 & p_5 & p_6 & p_7 & p_8 & p_9 \\
\end{bmatrix}
\]

\( K = [1 \ 2 \ 8], \ R = [5 \ 7 \ 8], \ n = 9 \ (K_3 = R_3, \ \text{series system}) \)

\( P = [p_1, p_2, p_3, p_4, p_5, p_6, p_7, p_8, p_9] \)

System Reliability \( =p_1*p_2*p_3*p_4*p_5*p_6*p_7*p_8*p_9 \)

\[
U\_p = [p_1 \ p_2 \ p_3 \ p_4 \ p_5 \ p_6 \ p_7 \ p_8 \ p_9]
\]
5 Conclusion

The presented algorithm allows one to estimate the influence of the reliability of individual elements on the reliability of the entire system (the element reliability importance). Though the reliability evaluation algorithm was provided, the usage of method is limited by its computational complexity. Obviously, this evaluation method is in fact an enumerative technique. As a result, if the number of system elements is large or the criteria $r_I$ is large, it will take extremely long period of time and RAM space for Matlab to calculate the system reliability. Simply speaking, if $r_I$ is larger than 20 (of course $n$ will be also larger than 20), the program can not get any results in a bearable long period of time. For instance, a consecutive (1, 2, 3)-out-of-(5, 7, 8)-from-9 system with $p = 0.8$, Matlab use 0.343 seconds to get the result. Table 1 shows that when $n$ is increasing, the time is getting larger and larger.
